Introduction to PySpark DataFrames

BIG DATA FUNDAMENTALS WITH PYSPARK

Upendra DevisettyScience Analyst, CyVerse

What are PySpark DataFrames?

- PySpark SQL is a Spark library for structured data. It provides more information about the structure of data and computation
- PySpark DataFrame is an immutable distributed collection of data with named columns
- Designed for processing both structured (e.g relational database) and semi-structured data (e.g JSON)
- Dataframe API is available in Python, R, Scala, and Java
- DataFrames in PySpark support both SQL queries (SELECT * from table) or expression methods (df.select())

SparkSession - Entry point for DataFrame API

- SparkContext is the main entry point for creating RDDs
- SparkSession provides a single point of entry to interact with Spark DataFrames
- SparkSession is used to create DataFrame, register DataFrames, execute SQL queries
- SparkSession is available in PySpark shell as spark

Creating DataFrames in PySpark

- Two different methods of creating DataFrames in PySpark
 - From existing RDDs using SparkSession's createDataFrame() method
 - From various data sources (CSV, JSON, TXT) using SparkSession's read method
- Schema controls the data and helps DataFrames to optimize queries
- Schema provides information about column name, type of data in the column, empty values etc.,

Create a DataFrame from RDD

```
iphones_RDD = sc.parallelize([
    ("XS", 2018, 5.65, 2.79, 6.24),
    ("XR", 2018, 5.94, 2.98, 6.84),
    ("X10", 2017, 5.65, 2.79, 6.13),
    ("8Plus", 2017, 6.23, 3.07, 7.12)
])
names = ['Model', 'Year', 'Height', 'Width', 'Weight']
iphones_df = spark.createDataFrame(iphones_RDD, schema=names)
type(iphones_df)
```

pyspark.sql.dataframe.DataFrame

Create a DataFrame from reading a CSV/JSON/TXT

```
df_csv = spark.read.csv("people.csv", header=True, inferSchema=True)

df_json = spark.read.json("people.json")

df_txt = spark.read.txt("people.txt")
```

- Path to the file and two optional parameters
- Two optional parameters
 - o header=True , inferSchema=True

Let's practice

DataFrame operators in PySpark

- DataFrame operations: Transformations and Actions
- DataFrame Transformations:
 - select(), filter(), groupby(), orderby(), dropDuplicates(), and withColumnRenamed()
- DataFrame Actions :
 - printSchema(), head(), show(), count(), columns, and describe()

Correction: printSchema() is a method for any Spark dataset/dataframe and not an action

select() and show() operations

• select() transformation subsets the columns in the DataFrame

```
df_id_age = test.select('Age')
```

• show() action prints first 20 rows in the DataFrame

```
df_id_age.show(3)
```

filter() and show() operations

• filter() transformation filters out the rows based on a condition

```
new_df_age21 = new_df.filter(new_df.Age > 21)
new_df_age21.show(3)
```

```
+----+
|User_ID|Gender|Age|
+----+
|1000002| M| 55|
|1000003| M| 26|
|1000004| M| 46|
+----+
only showing top 3 rows
```

groupby() and count() operations

groupby() operation can be used to group a variable

```
test_df_age_group = test_df.groupby('Age')
test_df_age_group.count().show(3)
```

orderby() Transformations

• orderby() operation sorts the DataFrame based on one or more columns

```
test_df_age_group.count().orderBy('Age').show(3)
```

```
+---+---+
|Age|count|
+---+---+
| 0|15098|
| 17| 4|
| 18|99660|
+---+----+
only showing top 3 rows
```

dropDuplicates()

• dropDuplicates() removes the duplicate rows of a DataFrame

```
test_df_no_dup = test_df.select('User_ID','Gender', 'Age').dropDuplicates()
test_df_no_dup.count()
```

5892

withColumnRenamed Transformations

withColumnRenamed() renames a column in the DataFrame

```
test_df_sex = test_df.withColumnRenamed('Gender', 'Sex')
test_df_sex.show(3)
```

```
+----+
|User_ID|Sex|Age|
+----+
|1000001| F| 17|
|1000001| F| 17|
|1000001| F| 17|
+----+
```

printSchema()

• printSchema() operation prints the types of columns in the DataFrame

```
test_df.printSchema()
```

```
|-- User_ID: integer (nullable = true)
|-- Product_ID: string (nullable = true)
|-- Gender: string (nullable = true)
|-- Age: string (nullable = true)
|-- Occupation: integer (nullable = true)
|-- Purchase: integer (nullable = true)
```

columns actions

• columns operator prints the columns of a DataFrame

```
test_df.columns
```

```
['User_ID', 'Gender', 'Age']
```

describe() actions

• describe() operation compute summary statistics of numerical columns in the DataFrame

```
test_df.describe().show()
```

BIG DATA FUNDAMENTALS WITH PYSPARK

Interacting with DataFrames using PySpark SQL

BIG DATA FUNDAMENTALS WITH PYSPARK

Upendra DevisettyScience Analyst, CyVerse

DataFrame API vs SQL queries

- In PySpark You can interact with SparkSQL through DataFrame API and SQL queries
- The DataFrame API provides a programmatic domain-specific language (DSL) for data
- DataFrame transformations and actions are easier to construct programmatically
- SQL queries can be concise and easier to understand and portable
- The operations on DataFrames can also be done using SQL queries

Executing SQL Queries

- The SparkSession sql() method executes SQL query
- sql() method takes a SQL statement as an argument and returns the result as DataFrame

```
df.createOrReplaceTempView("table1")

df2 = spark.sql("SELECT field1, field2 FROM table1")

df2.collect()
```

```
[Row(f1=1, f2='row1'), Row(f1=2, f2='row2'), Row(f1=3, f2='row3')]
```

SQL query to extract data

```
test_df.createOrReplaceTempView("test_table")
query = '''SELECT Product_ID FROM test_table'''
test_product_df = spark.sql(query)
test_product_df.show(5)
|Product_ID|
  P00069042
  P00248942
  P00087842
  P00085442|
  P00285442|
```

Summarizing and grouping data using SQL queries

```
test_df.createOrReplaceTempView("test_table")
query = '''SELECT Age, max(Purchase) FROM test_table GROUP BY Age'''
spark.sql(query).show(5)
  Age|max(Purchase)|
|18-25| 23958|
       23961
126-351
       23955|
 0-17|
       23960|
46-50
       23960
|51-55|
only showing top 5 rows
```

Filtering columns using SQL queries

```
test_df.createOrReplaceTempView("test_table")
query = '''SELECT Age, Purchase, Gender FROM test_table WHERE Purchase > 20000 AND Gender == "F"'''
spark.sql(query).show(5)
  Age|Purchase|Gender|
|36-45| 23792|
|26-35|
       21002| F|
|26-35|
        23595|
|26-35|
       23341
```

46-50 20771

only showing top 5 rows

Time to practice!

BIG DATA FUNDAMENTALS WITH PYSPARK

Data Visualization in PySpark using DataFrames

BIG DATA FUNDAMENTALS WITH PYSPARK

Upendra DevisettyScience Analyst, CyVerse

What is Data visualization?

- Data visualization is a way of representing your data in graphs or charts
- Open source plotting tools to aid visualization in Python:
 - Matplotlib, Seaborn, Bokeh etc.,
- Plotting graphs using PySpark DataFrames is done using three methods
 - pyspark_dist_explore library
 - toPandas()
 - HandySpark library

Data Visualization using Pyspark_dist_explore

- Pyspark_dist_explore library provides quick insights into DataFrames
- Currently three functions available: hist(), distplot(), and pandas_histogram()

```
test_df = spark.read.csv("test.csv", header=True, inferSchema=True)

test_df_age = test_df.select('Age')

hist(test_df_age, bins=20, color="red")
```

Using Pandas for plotting DataFrames

• It's easy to create charts from pandas DataFrames

```
test_df = spark.read.csv("test.csv", header=True, inferSchema=True)

test_df_sample_pandas = test_df.toPandas()

test_df_sample_pandas.hist('Age')
```

• Note: When you have large volumes of data, using toPandas() isn't recommended

Pandas DataFrame vs PySpark DataFrame

- Pandas DataFrames are in-memory, single-server based structures and operations on PySpark run in parallel
- The result is generated as we apply any operation in Pandas whereas operations in PySpark DataFrame are lazy evaluation
- Pandas DataFrame as mutable and PySpark DataFrames are immutable
- Pandas API support more operations than PySpark Dataframe API

HandySpark method of visualization

- HandySpark is a package designed to improve PySpark user experience
 - Easy data fetching
 - Distributed computation retained

```
test_df = spark.read.csv('test.csv', header=True, inferSchema=True)

hdf = test_df.toHandy()

hdf.cols["Age"].hist()
```

Let's visualize DataFrames
